

1. This document describes the progress made so far in the project.
2. This is the source of truth, it overrides everything written in the planning document "Building a Free Million Group Supervisor" !

Project Description -

1. The Problem - automate the check flow of the WhatsApp group "counting to million"
 - a. Group Rules:
 - i. Every message must contain a valid number! (previous_num+1) the rest of the message can be anything you want. The number can be written at any place in the message.
 - ii. The same person can't write more than one number in a row.
 - iii. Delete duplicate numbers - there should only be one copy of each number. Admins will delete incorrect messages.
 - iv. No commas in numbers. No Stickers/gifs allowed.
 - v. Mistakes can be fixed, as long as the counting flow stays intact.
 - b. The group is already running, with a current number around 410,000. Admins manually check each number, sometimes mistakes can be found hours later.
 - c. Ideally, mistakes should be found in the 15 minutes window when users can still edit the incorrect numbers. If not, the progress after the mistake will be lost.
2. The Solution - building a Headless Automation.
 - a. The journey of a message:
 - i. Filters - sent to the target group, not a sticker, has text, following rules.
 - ii. If it's valid (different sender, prev+1) - register to DB.
 - iii. Else, start the mistake window - wait 5 minutes for it to be edited. Then send an alert. All messages sent in the mistake window will be quickly checked to find a fix, then saved on a buffer and checked later.
 - iv. If the mistake was fixed by editing, check the buffer. If by someone else, it means buffer messages will be deleted, we don't need them anymore.
 - v. Immediate alerts will be sent only for stickers or double messages from the same sender. Otherwise we wait 5 minutes for the mistake window to close, as often people edit mistakes after a few seconds.
 - b. Architecture:
 - i. We will use Wuzapi for WhatsApp integration, RabbitMQ for message queuing, and a Python app for the actual logic. Previous numbers will be saved on SQLite DB .
 - ii. Wuzapi - acts as a connected device, like Whatsapp web. Uses the

- Noise Protocol to receive all events related to the whatsapp account.
- iii. Those services will run as docker containers, on an always-free Oracle ARM64 (Ampere A1 Compute) Ubuntu VM.
- iv. The code repository will sit on Github, and using Github Actions we will deploy the code to the VM and reload the services.
- v. Diagram below:

3. Progress:

- a. Phase 1 - preparing the environment, described on Readme file (github).
DoD -
 - i. all 3 services are running - basic python code can read and print messages from RabbitMQ.
 - ii. Wuzapi connection is able to send messages back to whatsapp.
- b. Phase 2 - logic engine V1:
 - i. One [main.py](#) script, with functions dedicated only to the million group.
 - ii. Later Refactored to handle edited messages.
 - iii. CI/CD added from Github actions into the machine.

c. Phase 3 - logic engine V2:

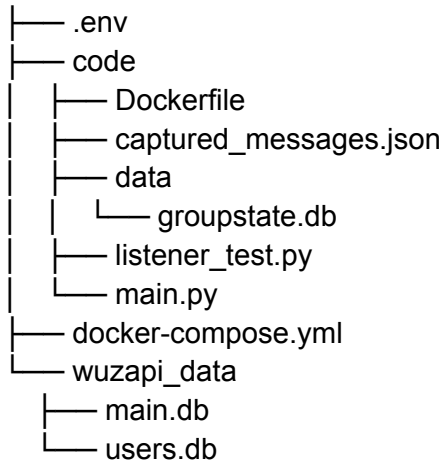

- i. Split the app into several scripts. [main.py](#) now initializes queue and route messages based on groups to specific scripts.
- ii. Utility functions shared between files. Admin actions added for immediate number override directly from phone.

Message example:

```
